

## Tree Anatomy: Leaf Shape & Form

Dr. Kim D. Coder, Professor of Tree Biology & Health Care / University Hill Fellow  
University of Georgia Warnell School of Forestry & Natural Resources

---

The shape of tree leaves is a primary way to identify tree species. The environment, resource availability, social / ecological interactions, and biology of trees and forests all impact leaf size and shape. Tree genetics set boundaries and help optimize leaf forms in the long-term, while stress, strain and physiological functions and dysfunctions constrain leaf forms in the short-term. Appreciating tree leaf macro-anatomy and morphology can help determine tree health, function, and identification.

Leaves can be highly variable in shape and size across a species, for localized gene sets, among individuals, and within a crown of a single tree. New leaves – old leaves, sun leaves – shade leaves, and/or preformed leaves – late-season leaves can all vary greatly in shape and size, or may not vary at all. Figure 1 shows leaf features used here to define tree leaves and aid in identification.

### Natural & Human Variation

Into a highly variable leaf world comes tree enthusiasts and dendrologists, each bringing local / regional familiarity and trained observing skills, to categorize and identify tree leaf shapes and associated species. Although science training demands accuracy and precision in observations, human subjectiveness is still present. One person's shape name may represent a different shape concept to someone else.

Native tree shape descriptions are almost as variable across individual observers as are natural leaf variations in the forest. In reviewing a number of different tree identification texts, one native tree species can be given one shape description, or many. This suggests our descriptive process seeks discrete standard stations of shape representing tree leaves and species, instead of the variable length, width, and form of a continuous shape / size gradients for leaves present in a forest.

### General Shape

A means of defining native tree leaf shape is through estimating a general overall shape without regard to various lobes, serrations, or undulations of a leaf blade. Two methods of reaching this observation goal are: 1) determine the ratio of leaf length to width; and, 2) define geometric leaf shape forms. Both methods demand observational discipline and precision over time and across observers. Both methods apply a two dimensional simplification to complex leaf shape and size. By using these two methods, an idea of the scope of natural variation for leaf forms can be estimated, and the morphological blending between shapes can be better defined.

### Geometry of Form

Broadleaved forms of leaves are called latifolius, and can vary in shape by changes in leaf length to leaf width ratios. This ratio is an estimate of general leaf shape and varies greatly between sun and shade leaves,

new and older leaves, and between individuals of the same species. The length to width ratio is one type of imaging for native tree leaves in two dimensions. Figure 2 provide a visual appreciation of length:width ratios where the leaf width is held constant and length varies across four different length:width ratios. Figure 3 helps visualize leaf / leaflet shape and size by holding the length constant while varying the leaf width.

Figure 4 shows the continuous gradient of leaf length to width ratios with the four standard stations of length:width ratios. Along the gradient general leaf / leaflet shape and size can be placed and determined if they reach or exceed thresholds of length:width ratios. Figure 5 provides a master list of both general geometric shape criteria and associated length:width ratio values for tree leaves and leaflets. Even though these shapes and values seem objective and easy to apply, observer variation can be great for some tree species.

The second means to describe native tree leaves is by the extent of the leaf blade or lamina. Place a geometric shape line around the outside outline of the leaf or leaflet, and estimate what form most closely describes the outline shape generated. There are six general forms which represent geometric derived leaf shapes:

1. **Orbicular** or rotund shapes are circular or round with a 1:1 length to width ratio. Oblate is a leaf wider than long with a <1:1 ratio. Suborbicular is a term for almost round having a <1.1:1 length to width ratio. Orbiculate has a <1.2:1 length to width ratio and are wide leaves, approaching round. Figure 6.

2. **Elliptical** shaped leaves are a narrow oval shape with base and tip sloped similarly, and is widest in the middle. Several forms of generic elliptical shapes vary by length to width ratios. Oval shapes have a >1.5:1 ratio and are broad elliptical in form, rounded at each end, with constantly curving margins. An elliptical form is considered to have a >3:1 ratio and is described as a narrow oval with constantly curving margins.

3. **Oblong** shaped leaves are longer than wide with parallel margins in the middle of its length, and ends similarly rounded. Oblong leaves can have a length to width ratio of >1.5:1, with parallel sides for the middle third of leaf length. Lanate shaped leaves have a ratio of >6:1 (3:1 to 9:1), with a long narrow form with parallel sides. Figure 7.

4. **Ovate** leaves are oval-like in shape with a longer than wide form (>1.5:1 length to width ratio), which is widest toward their base (i.e. egg-shaped or fat-based or fat-bottomed). Figure 8. A lanceolate leaf shape has a ratio of >6:1 (3:1 to 9:1), and is long and narrow, with its widest portion in the basal third of its length (i.e. long fat-based leaf). Subulate leaf shape (>10:1) is very narrow at its tip and expands little to be narrow at base (i.e. extremely long, barely tapered, fat-based leaf). Figure 9.

5. **Obovate** leaf shapes are oval-like, longer than wide, and widest toward its tip, with a length to width ratio of >1.5:1 (i.e. inverted egg-shaped form, or a fat-tipped / big-ended). Figure 10. Obelliptical leaves are almost elliptical (narrow oval-like) in form with their widest portion above / beyond leaf center with a length to width ratio of >2:1. Oblanceolate describes a leaf shape with a >6:1 (3:1 to 9:1) ratio, and is a long narrow oval like shape with its widest point in the apical third of the leaf (i.e. long fat-tipped leaf).

Obsubulate shaped leaves (>10:1) are very narrow at their base, expanding little to be narrow at their tip (i.e. extremely long, barely tapered, fat-tipped leaf).

6. **Linear** leaf shapes are very long and narrow, with a length to width ratio >10:1 regardless of where the widest portion of the leaf is located along its length. Figure 11. The margins are almost parallel. Angustifoliate is a historic term for narrow leaves. Subulate and obsubulate forms can also be considered linear.

Figure 12 summarizes leaf / leaflet shapes for field use in tree species identification. It must be noted word descriptions tend to over-inflate length:width ratios beyond actual measured length:width ratios of leaves. For example, authors using the term elliptic (>3:1 L:W ratio) may be viewing a leaf with a L:W ratio of <1.8:1, which approaching an oval shape. The cause of this perception issue for giving general shape names with implied larger L:W ratios than actual measured leaf values, is an observational bias.

### Special Leaves

Along with the previous listed geometric shape descriptions for leaves / leaflets, there are a number of special or complex shapes used in describing tree leaves. Figure 13 lists special leaf / leaflet shapes and definitions. Some are described below, but this list is not comprehensive, and hybrid forms and combinations exist and have been cited.

Cordate is a heart-shaped leaf which is a generally ovate form with a pointed tip and a heart-shaped notched base. Obcordate is an inverted heart-shaped leaf. Deltoid or deltate is a triangle-shaped leaf with its widest part at the base. Obdeltoid is an inverted triangle-shaped leaf.

Lyrate is a lyre-shaped leaf with a large rounded apical lobe and much smaller basal lobes. Panduriform is a fiddle-shaped leaf which is obovate with concave sides and two small basal lobes. Rhombic is a diamond-shaped leaf with four sides and two oblique angles (i.e. rhomboid form). Quadrangle is a square shape. Spatulate is a leaf with a spatula-shape, or is broad near its rounded tip with a quick narrowing taper to its base.

There are two arrowhead-shaped leaf forms usually described: hastate is a leaf with pointed basal lobes pointed outward; and, sagittate is a leaf with pointed basal lobes pointed downward. Two names for kidney shaped leaves, which are wider than long with a broad basal notch are nephroid or reniform. Some leaves have a shape which can appear cut-off or truncated. Praemorse leaf shapes have an abruptly terminated (truncate) end. A truncate leaf shape appears cut-off perpendicular to mid-vein. Figure 14 provides images of select special leaf / leaflet shapes with field codes.

### Native Tree Leaves

Figure 15 is a long multi-page list which provides leaf / leaflet length to width ratios, and associated descriptive geometric based names for native tree species with simple leaves. Figure 16 shows similar information for compound leaflets. In compound leaves, the listed ratios and shapes are for individual leaflets, not entire compound leaves.

Remember, all the descriptive terms listed are from an individual observer or text, and each are correct for the leaves examined. A summary or blending of multiple leaf descriptions, as well as location along the length:width ratio gradient, can provide the best visualization of a tree species' leaf / leaflet size and shape.

### Simply Compounded

Figure 17 provides a gradient (between 0.1:1 and 11:1 L:W ratio) along which native tree leaf length and width ratios vary. The length:width ratios are separated into simple leaves and compound leaflets. There appears to be an optimum leaf/leaflet shape for our native trees between 1.5:1 and 3.3:1 length:width ratio. Compound leaf leaflets have a much smaller range of length:width ratios than simple leaves.

Figure 18 shows the percent of shape descriptors used for native tree species leaves / leaflets which included 225 native tree species with 469 associated shape descriptors. Native trees with compound leaves had 85 different descriptors applied to leaflet shapes of 42 species. For compound leaflets, there were nine (9) single word entry descriptors, 23 double entry descriptors, and ten (10) triple descriptors for leaflets shape.

Native trees with simple leaves had 384 different shape descriptor terms applied for 183 tree species. For simple leaves, there were 26 single word entry descriptors, 114 double entry descriptors, 42 triple entry descriptors, and a single species whose composite shape was described by four descriptor terms across multiple authors. Note for many tree species, multiple authors could not determine shape with a single word concept, or for some trees, could not determine shape even with two word descriptions.

### Gymnos

There are few general gymnosperm / needle-like leaf shapes usually cited. Many gymnosperm trees have needle, scale, or awl shaped leaves. Needle shaped leaves are also described as acrose (meaning needle-shaped), or acicular (meaning slender needle-shaped). Needle is a general term for linear or acicular shaped leaves (i.e. *Pinus* spp.).

Scale-like leaves are small, short, overlapping, sessile and appressed to the twig. Awl-like or subulate leaves are short, narrow, stiff, and sharp pointed (i.e. *Juniperus* spp). Figure 19 provides native gymnosperm tree leaf / needle number per bundle, average length in inches, and length:width ratios. The length:width ratios for needle leaf trees are not highly descriptive.

### Confusions

When word concepts are used to define and describe biological structures under changing conditions over a single growing season or over many years, as well as for many individual trees and populations, confusion regarding leaf / leaflet shape definitions among observers will exist. Across a number of authors there has been variation and lack of precision using several shape descriptive terms. Three simple examples of descriptive confusion are given below:

- 1) Oval versus elliptical leaf shapes -- some authors use the term “broadly elliptical” shape, while others use the term “oval” shape to symbolize the same leaf shape. Some authors do not use the term “oval.”
- 2) Lance-shaped versus lanceolate leaf shapes -- some authors use “lance-shaped” for all ovate and lanceolate shapes, while others use separate “ovate” and “lanceolate” terms. Some authors use “broadly ovate” for “ovate” shapes, and “narrowly ovate” for “lanceolate.”
- 3) Elongated elliptical versus oblong leaf shapes -- some authors use the term “elongated elliptical” shape for “oblong” leaf shapes.

There are many other examples of indeterminate or variable shape definition among authors. Tree leaf shapes are in the eye, mind, and training of the beholder. Each tree observer can be quite precise for their own work, but shape definitions may not translate exactly across studies by other authors.

### Leaf / Leaflet Ends

Each tree leaf can be divided into three length portions: a middle third; an apical third; and, a basal third. Figure 20. The shapes of these specific leaf areas can help better define and describe a tree leaf for identification. Once a general leaf/leaflet shape is determined using methods above, the leaf / leaflet tip, base, and margin can be defined.

### Tips

The apex or tip area of a leaf or leaflet is the apical 33% of leaf length. A rounded leaf apex has a smooth arc at its tip. An obtuse leaf tip shape is pointed at an angle  $>90^\circ$ . An acute tip is short pointed with an angle  $<90^\circ$ . An acute leaf apex shape has many more subtle or more precise descriptions. Subacute is a leaf end with a slightly sharp and short pointed tip with an angle of  $<90^\circ$ . Cuspidate end shape has a sharp, short, stiff, thick point. Pungens end shape has a rigid, sharp, thick point.

An acuminate end shape has a long, narrow, gradually tapered pointed tip with an angle  $<90^\circ$ . Aristate end shapes are narrowed to a point with a stiff bristle at its tip. Aristulate shapes have a minute point with a stiff bristle at the tip. Attenuate is a slender, long-tapering tip with an angle  $<90^\circ$ . Caudate end shape has a tail-like, long, slender tip. Apiculate has a minute, short, slender, abrupt pointed tip. Figure 21. There exist differences in author perceptions and naming of apical tips between terms “acute” and “acuminate.”

### Notched

Three terms help describe leaf tips with notches: retuse has a shallow narrow notch in a round tip; emarginate has a shallow broad notch; and, obcordate has an inverse heart-shaped with wide notch in the tip. Figure 22. Leaf tips can appear truncated or cut-off, and three nearly identical terms can help describe this form: truncate is where the leaf end appear cutoff straight across, perpendicular to the midvein; and, abrupt or praemorse where the leaf tip is terminated abruptly or suddenly.

Figure 23 shows the percent of native tree species with different apical / tip forms. Note most native tree species leaf / leaflet apical tip descriptors are concentrated in the acute and acuminate forms.

### Very End

The most apical portion of a leaf or leaflet is the terminal end point. At the very end of the apical part of a leaf can be a characteristic apex tip or terminal point. An apex terminus is the end-most point of a leaf margin where the midvein ends.

There are five general terms usually used in describing the terminus or end-point of a leaf: mucronate is where the midvein ends with a short small peg-like bristle; mucronulate is where the midvein ends with a minute short small peg-like bristle; spinose is where the midvein ends with a sharp or dull spine; retuse is where the midvein ends at a shallow sinus; and, muticous is where the midvein end is blunt with no point or spine.

### Bases

Tree leaves and leaflets can have distinct shaped or forms of leaf bases. The leaf / leaflet attachment point to its supporting twig can be in three types. Leaf lamina can be attached directly to a twig and is called sessile. Lamina can also be attached to the twig with a petiole (simple leaf), or a rachis (compound leaf).

Figure 24. A leaf / leaflet base or bottom represents an area of the basal or bottom 33% of leaf length. Shapes are described around any protruding petiole or rachis, and represent just the leaf blade basal portion. Figure 25 shows selected leaf / leaflet basal forms.

Leaf base shapes can be rounded with a smooth arc, or form an obtuse angle ( $>90^\circ$ ). Leaf base shapes can be acute which is pointed with an angle of  $<90^\circ$ . A cuneate base is wedge-shaped with an angle  $<90^\circ$ . A decurrent leaf base shows a progressively decreasing angle as the petiole is approached, with an angle  $<90^\circ$ .

A truncate leaf base appears cutoff straight across the blade, perpendicular to the midvein. The term flat can also be used to describe the leaf lamina attached to its petiole / rachis at  $90^\circ$  to make a straight linear base. Cordate leaf bases have a sinus making a heart-shape. Figure 26 provides the percent of native tree species with different basal / base forms. Note base descriptors "rounded" and "cuneate" (wedge-shaped) comprise a large number of native tree species base shapes. There are differences between authors in using the terms "cuneate" and "tapered" base, which leads to description problems.

### Basal Peculiarities

Several terms are used to describe leaf base lobes or projections. A lobate leaf base has projections. Figure 27. Auriculate has small rounded lobes at the leaf base beside the petiole. Saggitate has large pointed lobes at the leaf base. Hastate has large pointed lobes facing away from base at  $>45^\circ$  angle. These lobes and projections may be further highlighted in leaves where the petiole attaches farther into the leaf blade than its base edge / margin. A peltate leaf base has a petiole which is attached in the middle of its leaf blade.

Some tree species have leaf / leaflet bases which are not symmetrical across the petiole connection. An oblique, dimidiate, or inequilateral leaf base is asymmetrical or lop-sided. A leaf base which is equal on both sides of the petiole junction is termed aequilateral. A leaf base is termed clasping when its blade partially or completely surrounds its twig.

### Definition Flexibility

Because leaf shapes are subject to environmental stress, physiological dysfunction, and pests, leaves on a tree may not form as expected. Teratology means abnormal development or mistakes in shape formation and growth (i.e. a teratological error or fault in leaf shape).

Figure 28 is a long list of different native tree species leaf / leaflet tips and base forms. Remember these are all tips and bases which have been listed by authors for each species. These descriptors should be considered, and used as, composite forms or shapes. Figure 29 shows the code key for the previous figure, giving word descriptors for each tip or base code value.

Figure 30 summarizes native tree species leaf / leaflet tip and base forms. There were more (~6%) base descriptors than tip descriptors used by different authors. Observers categorized leaf / leaflet tips predominantly into five (5) different forms, while roughly categorizing most bases into nine (9) different forms.

### Leaf / Leaflet Margins

Tree leaves have highly variable margins, many of which are unique and genetically conserved enough to help with species identification. Leaves can be divided into margins with no defining characters (i.e. straight, entire, or smooth), and margins which have projections or indentations.

Tree leaf margins are termed entire when the margin is a smooth edge without projections, indentations, or significant undulations. Additional terms for entire leaves are edentate which means no teeth or lobes, and smooth meaning an edge with no indentations. The words smooth and straight are generically used to represent entire leaf margins.

Lobed and toothed leaf margins can be important attributes for tree identifications. Lobes on a leaf margin have sinuses between them which are indented >25% the leaf blade distance to the mid-vein (or leaf radius). Toothed leaf margins have projections or points with spaces between indented <~10% the leaf blade distance to the mid-vein (or leaf radius). Generally lobes are large and consume large leaf surface areas, while marginal teeth are small running along the leaf edge.

Some leaf margins have highly irregular patterns of indentations and projections appearing damaged, chewed, or eroded. This leaf margin form is called erose. Erose leaf margins can be divided into two general forms: eroseulate which has slightly irregular teeth and sinuses appearing damaged, chewed, or eroded; and, suberose which has somewhat gnawed or eroded teeth. Figure 31.

Leaf margins can be covered to various degrees with trichomes. The general term for a leaf edge with trichomes is termed fringed. There has been four terms used for a fringed leaf margin, not including more detailed trichome descriptions. A ciliate leaf margin has a fringed edge with short trichomes. A ciliatulate margin is a fringe edge with widely spaced and dispersed trichomes. Ciliolate leaf margins are fringed with minute trichomes. Fimbriate is a generic term for a fringed leaf margin.

### Marginal Forms

Leaf margins can have edge waves, which are regular shallow projections and sinuses, or waves along their margin. Waved leaf margins are generally divided into three forms: (Figure 32) repand waved margins which are slightly wavy toward and away from midvein along the margin; sinuate waved margins which are shallow, gentle non-vascularized projections and sinuses; and undulate waved margins which are down (toward abaxial surface) and up (toward adaxial surface) gentle curves, but with no strongly repeating projections or sinuses of a wave. Figure 33 lists native tree species with undulate, sinuate, and repand margins.

There are several confusing uses of marginal wave terminology by a number of authors. The term “wavy” has been used for undulate, sinuate, and repand. In some cases, “wavy” has been used for crenate teeth. The word “wavy” is not a precise nor effective term.

Some tree leaves have leaf margins which appear to be rolled, with the margin turned under or rolled upward towards itself. Figure 34. Rolled leaf margins can be characteristic of a number of trees. There are four rolled leaf margins usually cited: evolute margins are rolled downward toward abaxial side of leaf; revolute margins are rolled downward toward abaxial side of a leaf; inrolled margins are curled up and inward toward the adaxial side of a leaf; and, involute margins are rolled up and inward toward adaxial side of leaf. Figure 35.

The total number and percent of native tree species with “wavy” or “rolled” edges / margins are given in Figure 36. A significant number (24%) of native tree species leaves / leaflets have some form of undulate, sinuate, or repand margins

### Leaf / Leaflet Teeth

Tree leaf margins can have a variety of teeth and crenations. A leaf is considered toothed if only one tooth is displayed. A leaf tooth is a marginal (not at the tip) vascularized, pointed projection with associated sinuses, with the length of the sinus less than ~10% of the distance between the leaf margin and mid-vein. With each leaf tooth projection is a leaf sinus indentation. Leaf teeth sinuses are admedial indentations, incisions, or embayments from a leaf / leaflet margin immediately in front of, or between, any exmedial projections like teeth, which can have either a rounded or angular bottom.

There are three general tooth types: dentate; serrate; and, crenate. Dentate marginal teeth are pointed and aligned perpendicular to the leaf margin. Serrate marginal teeth are pointed and inclined or directed toward the leaf tip. Serrate or serrated are generically used to represent leaves with both dentate and serrate leaf

margins. Crenate marginal teeth have smooth, shallow, rounded projections and are not pointed. Figure 37. Crenate marginal projections should not be confused with repand or sinuate margins.

### Teeth Types

Dentate teeth are pointed perpendicular to the leaf margin. Dentate leaf margins can differ in the shape or form of each tooth tip. Cited dentate tip shapes include: acute, obtuse, acuminate, attenuate, mucronate, and glandular. Another form of dentate teeth is termed denticulate or denticle, having minute teeth pointed perpendicular to the leaf margin.

Serrate teeth forms are pointed and inclined toward the leaf tip. Serrate leaf margins differ in each tooth tip shape. Cited serrate tip shapes include: acute, obtuse, acuminate, attenuate, mucronate, and glandular. Serrate teeth forms can also be further described by a number of terms. Serrulate has small teeth angled toward tip. Incurved has long sharp teeth curved back toward the margin. Double serrate has large teeth, with smaller teeth on each large tooth. Biserrate is another name for double serrate. Glandular serrate has small teeth tipped with glands, or in some cases can appear as glands alone. Remotely serrate has small widely scattered teeth along a leaf margin.

Crenations are marginal (not at the leaf tip) with smooth rounded vascularized projections (i.e. teeth) without points. Associated sinuses are less than ~10% of the distance between the leaf margin and mid-vein. Crenate means leaf marginal projection tips are rounded with no point. Two types of crenate projections are usually cited: dentate crenate with rounded projections perpendicular to the leaf margin; and, serrate crenate with rounded projections arising at an angle to the leaf margin. Crenulate is a form with minute, gently rounded projections. Gimped is another term historically used for crenate, meaning rounded projections. Scalloped is a form of crenate projections which are very gently rounded. Again, crenations are marginal teeth or projections, which should be differentiated from undulate, repand or sinuous margins.

### Teeth Gaps

The spacing between each single tooth or projection can be regular and similar. Spacing can also be irregular, with spaces between teeth or crenations wide and sparse, or narrow and dense. The number and pattern of teeth and projections can aid in leaf identification. In addition to single tooth and crenation spacing, multiple patterns may overlay each other, generating compound double or triple forms. A double form has teeth or crenations with smaller teeth or crenations on each of their edges.

Some leaf margins have teeth with sharp, elongated points designed to shed water. These drip points or awn points appear on leaf ends or margins, and facilitate rain and dew shedding off the leaf / leaflet tip or end. A leaf margin or tooth tip is termed awned when there is a stiff bristle on the end. An elongated margin point can be considered a drip point.

### Leaf / Leaflet Lobes

A number of tree leaves have lobes (i.e. lobation). A leaf lobe is a exmedial marginal leaf projection (not at the tip), and an associated sinus which is more than 25% of the distance from the projection tip to the midvein. A leaf / leaflet is considered lobed if only one lobe exists.

Between leaf lobes are lobe sinuses. A leaf lobe sinus is an admedial indentation, incision, or embayment from the leaf margin immediately in front of, or between, any exmedial projections like lobes. Sinuses can have either a rounded or angular bottom. Determining lobe and sinus shapes and forms can help identify many tree leaves.

### Lobe Types

Lobes on leaves have many forms and shapes. Common lobe patterns on leaves are palmately lobed and pinnately lobed. Figure 38. Palmately lobed leaves have major veins and lobe axes radiating from the leaf base. Palmate lobing can be divided into two additional forms: palmatisect, which is a palmately lobed simple leaf where incised sinuses reach almost to the main vein; and, palmifid, with palmately arranged moderate depth sinuses. Figure 39.

Pinnately lobed leaves have major veins and lobe axes arising along the mid-vein. Figure 40. Pinnate lobing can be divided into three additional forms: pinnatisect, where a pinnately lobed simple leaf has incised sinuses which reach almost to the midvein; pinnatifid, where a pinnately lobed leaf has deep sinuses but not to the midvein; and, pinnatilobate, where leaves have shallow pinnate lobes. Figure 41.

### Lobe Shapes & Size

There are a number of specific shaped lobing forms. A combination form is termed a palmately and pinnately lobed leaf, where at least one palmate leaf lobe has pinnate lobes. Other special leaf lobing types include: bilobed with two lobes; bipartite which is deeply divided into two lobes; cleft which is a deeply cut leaf at least halfway to mid-vein with narrow sharp-ended sinuses; dissected lobed leaves are deeply divided into numerous narrow lobes; incised with very deeply cut lobes almost to mid-vein with narrow sharp-ended sinuses; lacerate appearing cut or clefted irregularly as if torn; lacinate with pointed lobes having deep narrow irregular sinuses; lobulate lobed leaves which are divided into small lobes; lobule lobing with small lobes on a larger lobe; multifid with a leaf cut into many narrow segments or lobes; and, runcinate where lobes are angled back toward the leaf base. Figure 42. The use of these different special leaf lobe terms can demonstrate subtle differences, or can be more of an author's preference for use or generalizing.

### Margin Types

Figure 43 provides a list of native tree species with entire margins. Remember some of these species can have both serrate, lobed, and entire margins. In these cases, species were listed in multiple margin form lists. Figure 44 lists native tree species generating serrate margins of various types. Figure 45 lists native tree species with lobed margins, with or without serrations. The number of lobes present for each tree species is also listed.

Figure 46 shows an accounting of entire, serrate, and lobed native tree species, and associated different combinations cited of margin forms. Note a majority (60%) of native tree species examined generate various types of serrated leaves and leaflets.

### Shade Impacts

The broad general shape of the entire leaf or leaflet can be determined by fitting a leaf within the bounds of a geometric shape. The effective shade diameter of a leaf or leaflet is determined by the area of the largest oval which can fit within a leaf outline which does not cross the leaf margin (i.e. does not include leaf areas in teeth or lobes) converted into an equivalent circular area. This effective shade diameter of a leaf can be used to determine the direct shade cone (umbra) distance behind a leaf opposite the sun.

This direct shade distance (~65X effective shade diameter behind a leaf) defines an area with a limited amount of sunlight available for other leaves and other trees behind the first. The indirect shade area or volume (penumbra -- partial shade) may contain a significant amount of light energy of varying photosynthetic quality including partial shade and sunflecks, which some resource tolerant tree species can utilize. Leaf size and shape

---

impact direct and indirect shade density and extent, and so impacts available light resources for the ecological space behind / beneath. Figure 47.

## Conclusions

Tree leaf / leaflet shapes and sizes are diverse and variable. All leaves perform a number of similar tasks both internally and externally, but these functions can be effectively completed using many different naturally honed shapes and sizes. Trees have generated many ways for leaves to be successful. The appearance of tree leaves can help identify tree species, genera, and growth problems. Tree leaves serve as windows into tree health and lineage.

Figure 4: Continuous gradient of leaf length:width ratios and major leaf aspect thresholds.

<b>general / geometric leaf shape</b>	<b>length to width ratio</b>
<b><u>Orbicular / Rotund</u></b> (circular / round)	<b>1:1 ratio</b>
<b>Oblate</b> (wider than long)	<b>&lt;1:1 ratio</b>
<b>Suborbicular</b> (almost round)	<b>&lt;1.1:1 ratio</b>
<b>Orbiculate</b> (wide)	<b>&lt;1.2:1 ratio</b>
<b><u>Elliptical or Narrow Oval</u></b> (widest in middle – margins curved)	
<b>Oval</b> (broad elliptical)	<b>&gt;1.5:1 ratio</b>
<b>Elliptic</b> (narrow oval)	<b>&gt;3:1 ratio</b>
<b><u>Oblong</u></b> (parallel margins / straight sides in middle third of leaf)	
<b>Oblong</b>	<b>&gt;1.5:1 ratio</b>
<b>Lanate</b> (long narrow)	<b>&gt;6:1 ratio (3:1 to 9:1)</b>
<b><u>Ovate</u></b> (widest in basal third of leaf – egg-shaped or fat-based)	
<b>Ovate</b> (oval-like)	<b>&gt;1.5:1 ratio</b>
<b>Lanceolate</b> (long narrow oval-like)	<b>&gt;6:1 ratio (3:1 to 9:1)</b>
<b>Subulate</b> (barely tapered, fat-based)	<b>&gt;10:1 ratio</b>
<b><u>Obovate</u></b> (widest in apical third of leaf – fat-tipped / wide-ended)	
<b>Obovate</b> (oval-like)	<b>&gt;1.5:1 ratio</b>
<b>Obelliptical</b> (narrow oval-like)	<b>&gt;2:1 ratio</b>
<b>Ob lanceolate</b> (long narrow oval-like)	<b>&gt;6:1 ratio (3:1 to 9:1)</b>
<b>Obsubulate</b> (barely tapered, fat-ended)	<b>&gt;10:1 ratio</b>
<b><u>Linear</u></b> (extremely long & narrow -- regardless of widest portion)	<b>&gt;10:1 ratio</b>

Figure 5: General tree leaf / leaflet blade shape names with length to width ratios.

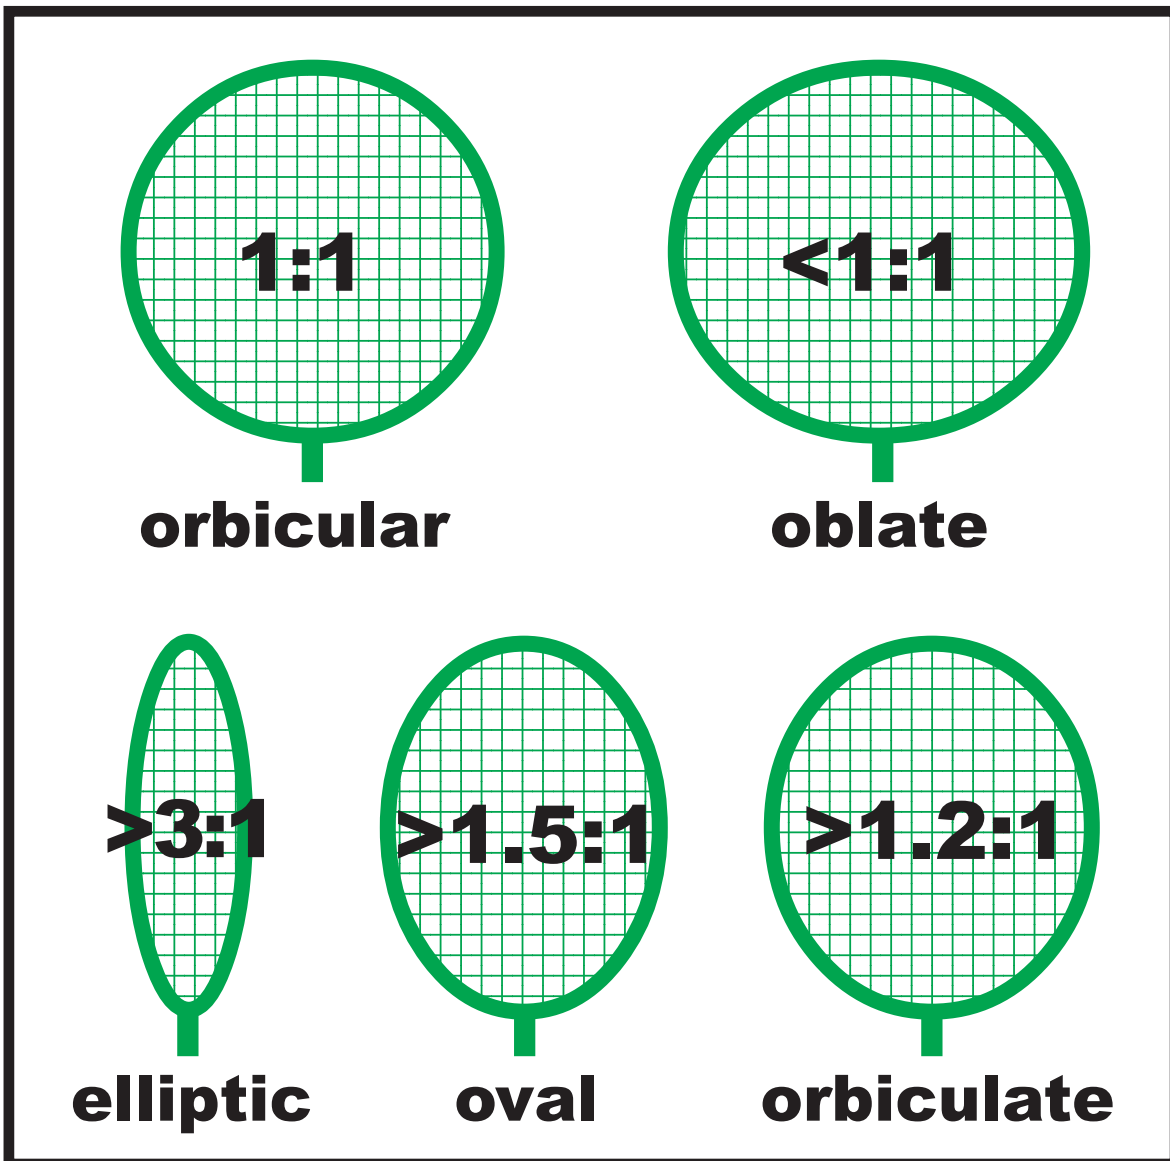

Figure 6: Listing of general tree leaf blade shapes which are widest in the middle with curved margins, associated length to width ratios, and geometric based names.

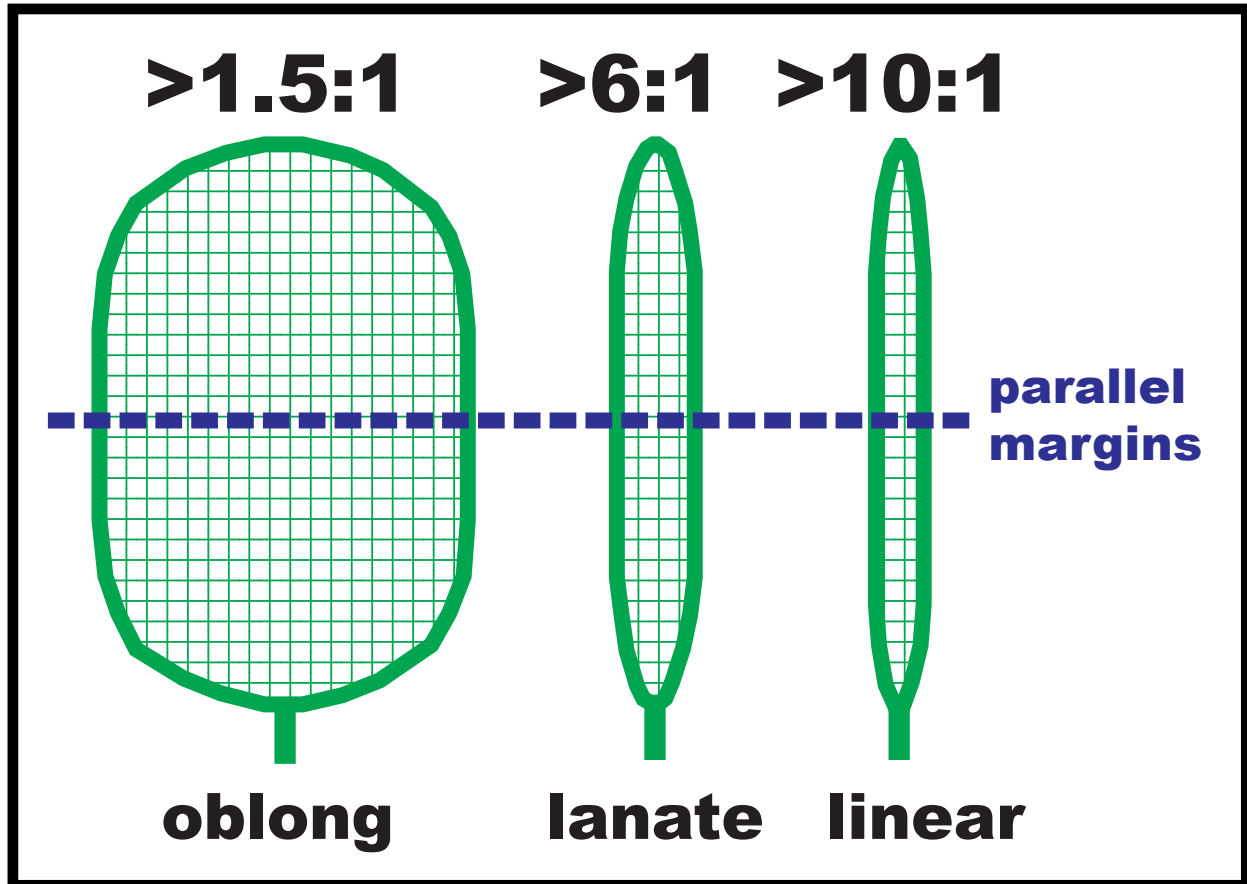

Figure 7: Listing of general tree leaf blade shapes which are widest in the middle with parallel margins, associated length to width ratios, and geometric based names.

Figure 8: Tree leaf blade shape names are based upon general forms determined by where along a leaf length it is widest -- across the middle, toward its tip, or toward its base.

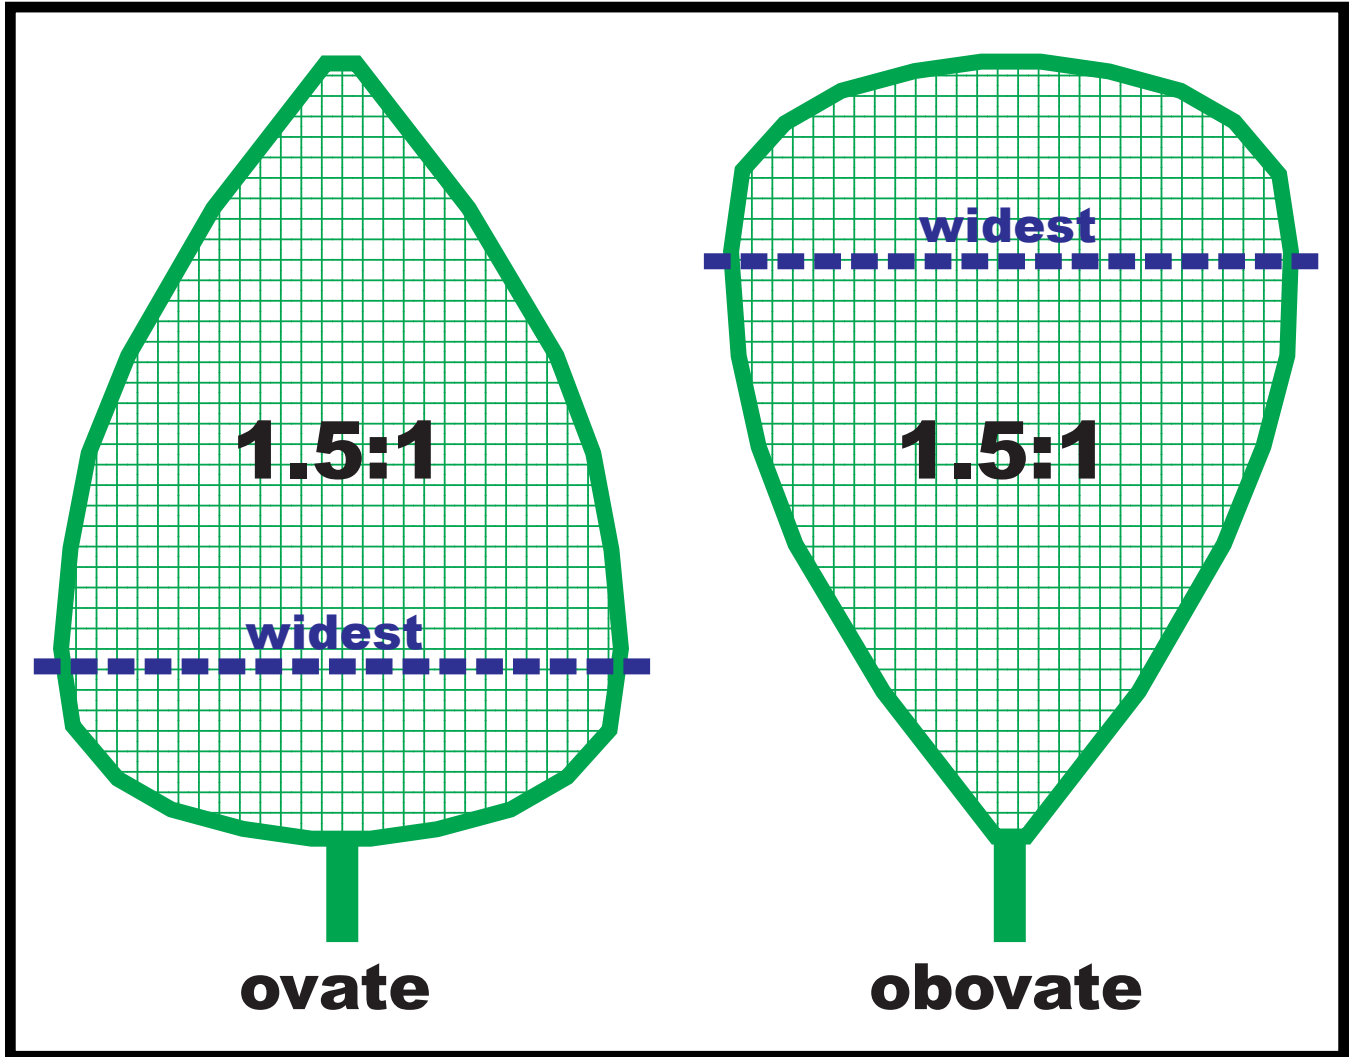

Figure 9: General oval-like tree leaf blade shapes which are widest at either end, with length to width ratios, and names.

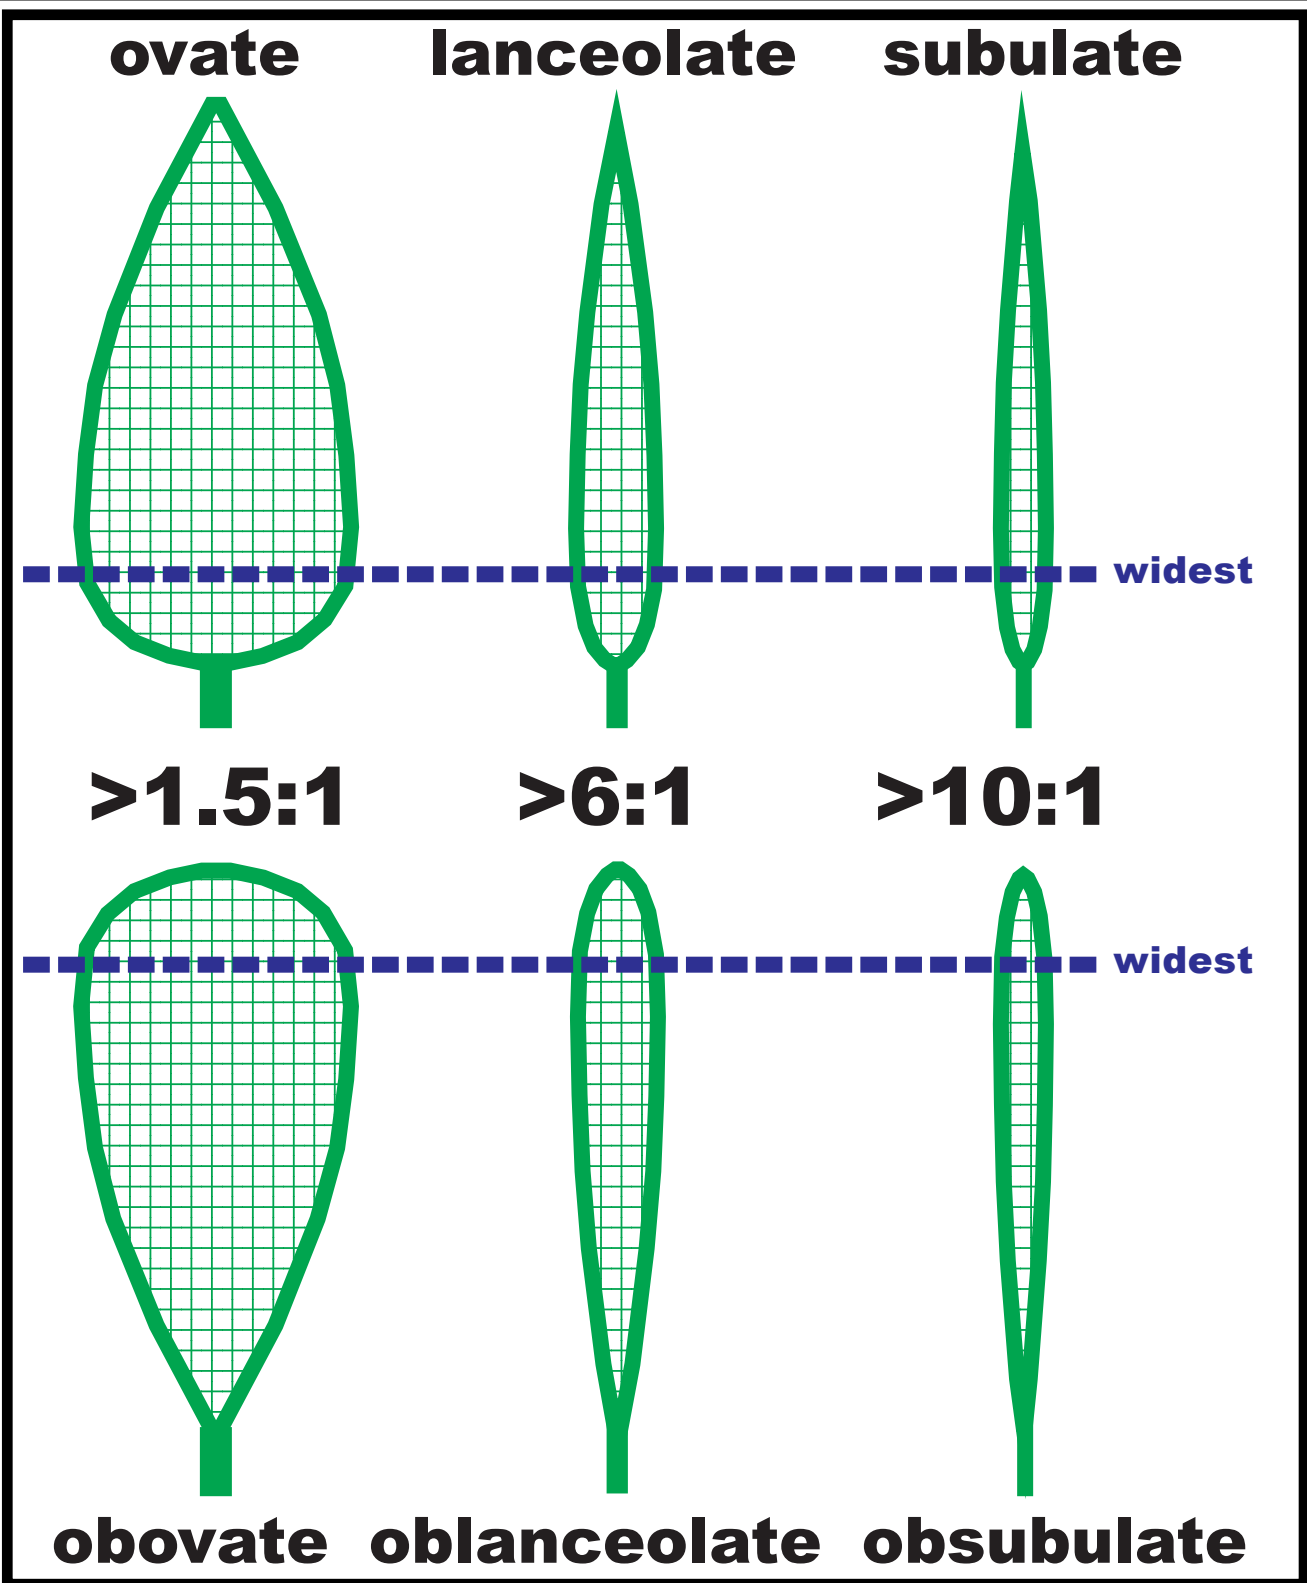

Figure 10: Listing of general oval-form tree leaf blade shapes which are widest at either end, with associated length to width ratios, and geometric based names.

The prefix “ob” means away from the leaf base.

Figure 11: Long, narrow tree leaf blade shapes which can be widest anywhere along their length, with associated length to width ratio, and generic name.

# GENERIC LEAF SHAPES

Figure 12: Field guide of generic leaf / leaflet forms, geometric based shape names, and associated code numbers.

## Special Leaf / Leaflet Shapes

name	description
<b>Cordate</b>	= heart-shape – pointed tip & heart-shaped wide notched base
<b>Obcordate</b>	= inverted heart-shape
<b>Deltoid / Deltate</b>	= triangle-shaped -- widest at base
<b>Obdeltoid</b>	= inverted triangle-shape
<b>Lyrate</b>	= lyre-shaped – large rounded apical lobe & much smaller basal lobes
<b>Panduriform</b>	= fiddle-shaped obovate with concave sides & two small basal lobes
<b>Rhombic</b>	= diamond-shaped -- four sides & two oblique angles (rhomboid)
<b>Spatulate</b>	= spatula-shape – broad near rounded tip with quickly narrowing taper to base
<b>Hastate</b>	= arrow-head – basal lobes pointed outward
<b>Sagittate</b>	= arrow-head – basal lobes pointed downward
<b>Nephroid / Reniform</b>	= kidney-shaped – wider than long with broad basal notch
<b>Praemorse</b>	= abruptly terminated (truncate) apical end

Figure 13: Selected special tree leaf / leaflet blade shape names with simple descriptions.

Figure 14: Special tree leaf / leaflet forms, shape name, and code letter.

scientific name	common name	L:W	description

Figure 26: Percent of native tree species with leaves / leaflets having specific base forms or shapes.

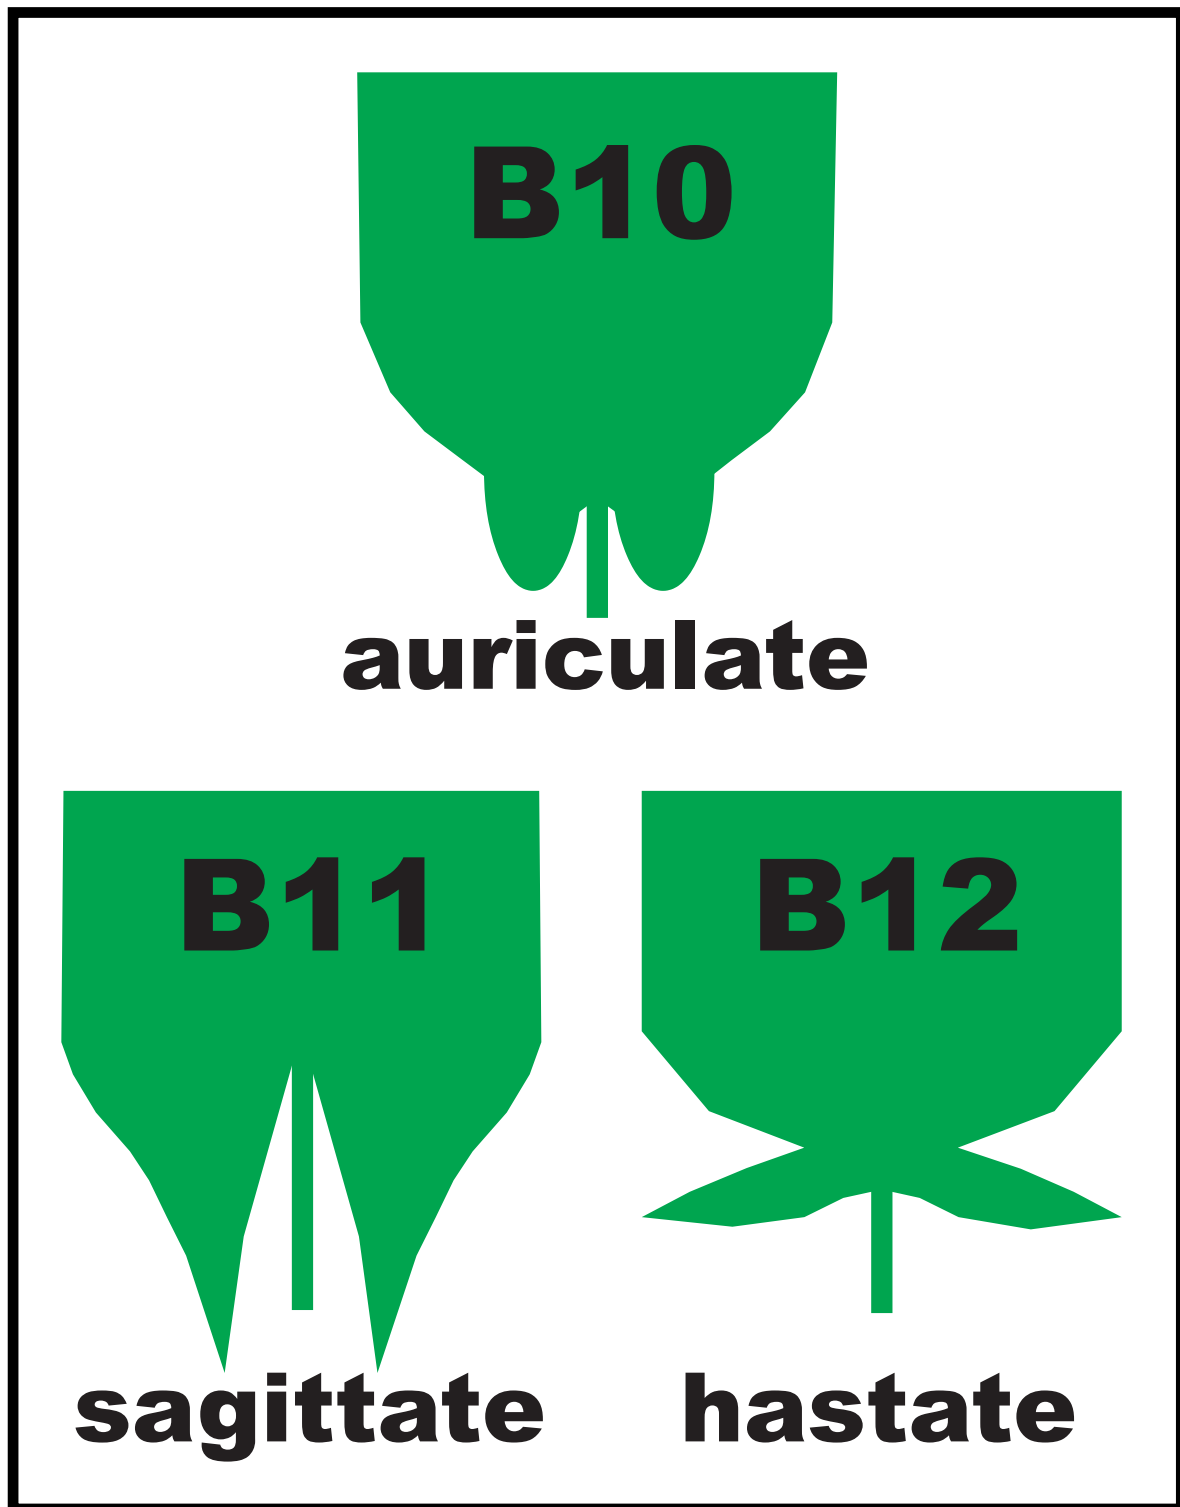

Figure 27: Basal lobes (lobate projections) on tree leaf / leaflet margins.

scientific name	common name	tip form	base form
<i>Acer barbatum</i>	Southern sugar maple	A1 A3	B7
<i>Acer leucoderme</i>	chalk maple	A1 A5	B7
<i>Acer negundo</i> *	boxelder	A5	B1
<i>Acer nigrum</i>	black maple	A5	B7
<i>Acer pensylvanicum</i>	striped maple	A5	B1 B7
<i>Acer rubrum</i>	red maple	A3 A5	B6 B7
<i>Acer saccharinum</i>	silver maple	A5	B6
<i>Acer saccharum</i>	sugar maple	A5	B6 B7
<i>Acer spicatum</i>	mountain maple	A3 A5	B7
<i>Aesculus flava</i> *	yellow buckeye	A3 A5	B3 B4 B9
<i>Aesculus glabra</i> *	Ohio buckeye	A5	B4 B9
<i>Aesculus parviflora</i> *	bottlebrush buckeye	A5	B2 B4
<i>Aesculus pavia</i> *	red buckeye	A3	B3 B9
<i>Aesculus sylvatica</i> *	Georgia buckeye	A3	B9
<i>Alnus serrulata</i>	hazel alder	A1 A2	B1
<i>Amelanchier arborea</i>	serviceberry	A2 A3	B1 B7
<i>Aralia spinosa</i> *	devil's walkingstick	A3 A5	B1 B4
<i>Asimina parviflora</i>	dwarf pawpaw	A3 A5	B4
<i>Asimina triloba</i>	pawpaw	A3 B3	B5 B9
<i>Baccharis halimifolia</i>	Eastern baccharis	A2 A3	B5 B9
<i>Betula alleghaniensis</i>	yellow birch	A3 A5	B1 B7 B8
<i>Betula lenta</i>	sweet birch	A3 A5	B1 B7
<i>Betula nigra</i>	river birch	A3	B2 B4
<i>Carpinus caroliniana</i>	S. American hornbeam	A3 A5	B1 B8
<i>Carya aquatica</i> *	water hickory	A5	B1 B3
<i>Carya australis</i> *	Southern shagbark hickory	A3 A5	B4 B9
<i>Carya cordiformis</i> *	bitternut hickory	A5 B1	B4 B9
<i>Carya glabra</i> *	pignut hickory	A3 A5	B1 B4
<i>Carya laciniosa</i> *	shellbark hickory	A3 A5	B4 B9
<i>Carya myristiciformis</i> *	nutmeg hickory	A3 A5	B4 B9
<i>Carya ovalis</i> *	red hickory	A2 A5	B1 B8
<i>Carya ovata</i> *	shagbark hickory	A3 A5	B4
<i>Carya pallida</i> *	sand hickory	A3 A5	B4 B9
<i>Carya tomentosa</i> *	mockernut hickory	A3 A5	B4 B8
<i>Castanea dentata</i>	American chestnut	A4 A5	B3
<i>Castanea pumila</i>	chinquapin	A3	B1 B8 B10
<i>Catalpa bignonioides</i>	Southern catalpa	A5	B7
<i>Celtis laevigata</i>	sugarberry	A3 A5	B1 B3
<i>Celtis occidentalis</i>	hackberry	A5	B1 B2 B8
<i>Celtis tenuifolia</i>	Georgia hackberry	A3	B1 B8
<i>Cephalanthus occidentalis</i>	buttonbush	A3 A5	B1 B3 B4 B9

scientific name	common name	tip form	base form
<i>Cercis canadensis</i>	redbud	A3	B6 B7
<i>Chionanthus virginicus</i>	fringetree	A3	B4 B5 B9
<i>Cladrastis kentukea</i> *	yellowwood	A3	B1
<i>Clethra acuminata</i>	sweet pepperbush	A3 A5	B2 B3
<i>Cliftonia monophylla</i>	buckwheat tree	A1 A2 A13 A14	B4 B9
<i>Cornus alternifolia</i>	alternate-leaf dogwood	A5 B1	B4
<i>Cornus florida</i>	flowering dogwood	A3 B1	B5
<i>Cornus foemina</i>	swamp dogwood	A3 A5 B1	B3
<i>Cotinus obovatus</i>	smoketree	A1 A2 A13	B3
<i>Crataegus aestivalis</i>	mayhaw	A2 A3	B9
<i>Crataegus aprica</i>	sunny hawthorn	A2 A3	B4 B5
<i>Crataegus calpodendron</i>	pear hawthorn	A3 A5	B3
<i>Crataegus crus-galli</i>	cockspur hawthorn	A2 A3	B9
<i>Crataegus flava</i>	yellow hawthorn	A1 A2 A3	B4 B9
<i>Crataegus intricata</i>	Biltmore hawthorn	A2 A3	B1 B3
<i>Crataegus marshallii</i>	parsley hawthorn	A2 A3	B4 B6
<i>Crataegus phaenopyrum</i>	Washington hawthorn	A3	B4 B6
<i>Crataegus pruinosa</i>	waxy-fruit hawthorn	A3	B1 B2
<i>Crataegus pulcherrima</i>	beautiful hawthorn	A3	B9
<i>Crataegus punctata</i>	dotted hawthorn	A1 A2	B5 B9
<i>Crataegus spathulata</i>	littlehip hawthorn	A1	B9
<i>Crataegus triflora</i>	three-flower hawthorn	A3	B1 B2
<i>Crataegus uniflora</i>	dwarf hawthorn	A1 A2	B4 B9
<i>Crataegus viridis</i>	green hawthorn	A3	B9
<i>Cyrilla parvifolia</i>	littleleaf titi	A2 A3	B4 B9
<i>Cyrilla racemiflora</i>	swamp titi	A1 A2 A3 A13	B4
<i>Diospyros virginiana</i>	persimmon	A3 A5	B3
<i>Elliottia racemosa</i>	Georgia plume	A3 A6	B5
<i>Euonymus atropurpureus</i>	burningbush	A5	B1 B3 B4
<i>Fagus grandifolia</i>	American beech	A3 A5	B4
<i>Forestiera acuminata</i>	swamp-privet	A3 A5	B3 B4 B9
<i>Forestiera segregata</i>	Florida-privet	A1 A2	B3 B9
<i>Franklinia alatamaha</i>	Franklin tree	A3	B9
<i>Fraxinus americana</i> *	white ash	A3	B1
<i>Fraxinus caroliniana</i> *	Carolina ash	A5	B1 B4
<i>Fraxinus pennsylvanica</i> *	green ash	A3 A5	B3 B4
<i>Fraxinus profunda</i> *	pumpkin ash	A3 A5	B1 B4
<i>Fraxinus quadrangulata</i> *	blue ash	A5	B1 B3
<i>Gleditsia aquatica</i> *	water locust	A1	B1
<i>Gleditsia triacanthos</i> *	honeylocust	A1	B1
<i>Gordonia lasianthus</i>	loblolly bay	A2 A3	B4

**LEAF / LEAFLET  
TIP & BASE  
DESCRIPTORS  
= 815**

**TIP DESCRIPTORS  
= 47% (5 dominant forms)**

**BASE DESCRIPTORS  
= 53% (9 dominant forms)**

Figure 30: Total number of tip and base descriptors for 225 native tree species leaves and leaflets from all sources.

# Leaf Margin Appearance

margin name	description
<b>erose</b>	= margin edge minutely serrate & irregular -- appears damaged or chewed
<b>sinuous</b>	= margin edge has smooth shallow curves with no vein ends
<b>undulate</b>	= margin edge has smooth shallow curves up & down across the plane of the leaf blade
<b>revolute</b>	= margin edge turned down or rolled in abaxial direction
<b>involute</b>	= margin edge turned up or rolled in an adaxial direction

Figure 31: Selected special tree leaf / leaflet blade margin appearance names and simple descriptions.

Figure 32: Wavy tree leaf / leaflet margin edges.  
(Note -- not lobes or crenate teeth)

# UNDULATE, SINUATE, REPAND

<i>Acer leucoderme</i>	chalk maple	<i>Persea borbonia</i>	red-bay
<i>Acer nigrum</i>	black maple	<i>Prunus angustifolia</i>	Chickasaw plum

with revolute or involute margins  
( i = involute leaves)

## **TREE LEAF / LEAFLET MARGINS**

**UNDULATE, SINUATE,  
AND/OR REPAND  
= 55 (24%)**

**REVOLUTE (18) OR  
INVOLUTE (1)  
= 19 ( 8%)**

Figure 36: Native tree leaf / leaflet margin forms.  
Values are number of species and percent of  
all 225 native tree species surveyed.

Figure 37: Tree leaf / leaflet margin forms, identification code, and name -- as edge-viewed from above.

Figure 38: Two primary lobe forms on tree leaves / leaflets.

Figure 39: Two types of palmate lobe forms, based upon sinus depth to mid-vein, on tree leaves / leaflets.

Figure 40: Defining a pinnate lobe and associated sinus on a tree leaf / leaflet margin.

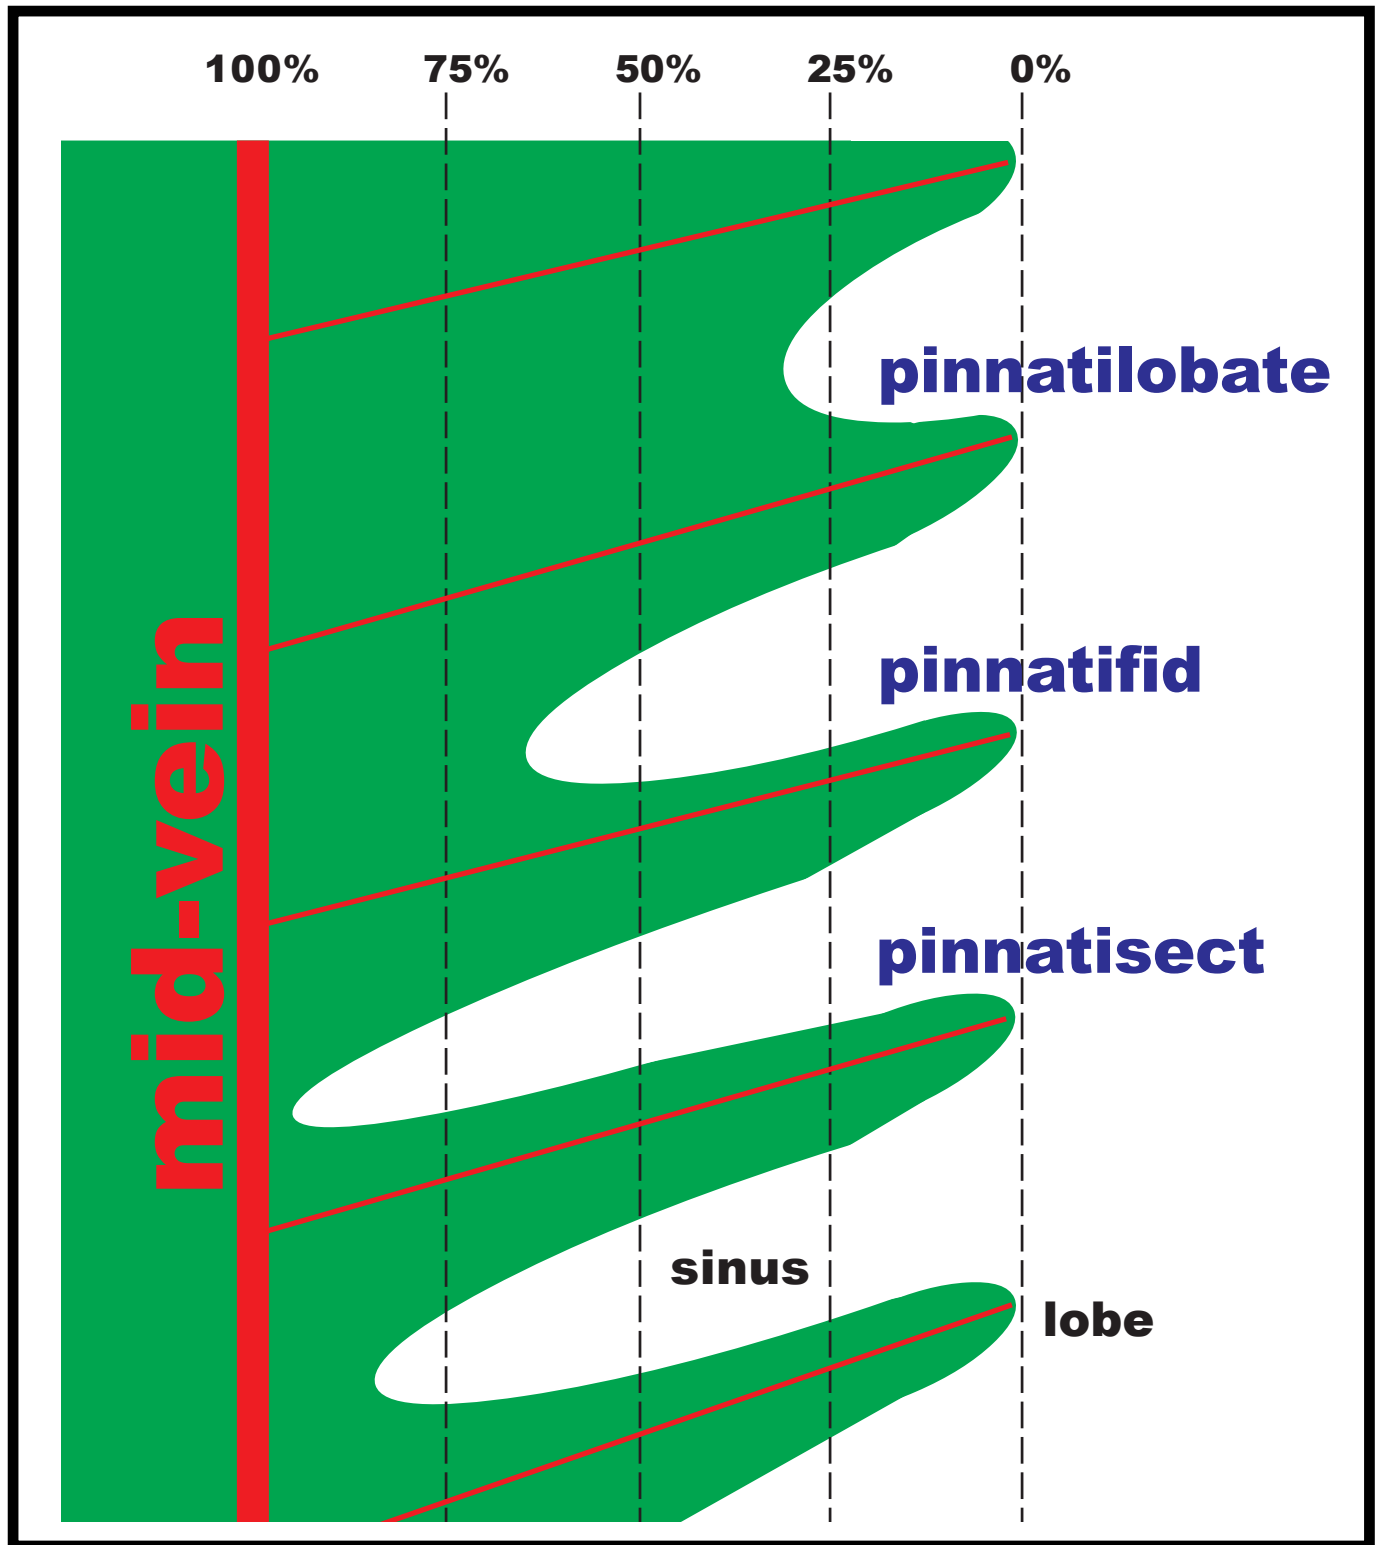

Figure 41: Defining types of pinnate lobes, based upon sinus depth toward mid-vein, on tree leaf / leaflet margins.

## Specialized Leaf / Leaflet Lobe Forms

### **palmately & pinnately lobed**

= combination form with at least one palmate lobe having pinnate lobes

**bilobed** = two lobes

**bipartite** = deeply divided into two lobes

**cleft** = deeply cut at least halfway to mid-vein with narrow sharp-ended sinuses

**dissected** = deeply cut with numerous narrow lobes

**incised** = deeply cut almost to mid-vein with narrow sharp-ended sinuses

**lacerate** = appear cut or clefted irregularly as if torn

**laciniate** = pointed lobes with deep narrow irregular sinuses

**lobulate** = divided into small lobes

**lobule** = small lobes on a larger lobe

**multifid** = many narrow segments or lobes

**runcinate** = lobes angled back toward leaf base

(Note: these terms represents subtle differences / researcher preferences)

Figure 45: Native tree species leaves with lobed margins.

The numeric values listed are the range of lobes found on leaves.

## TREE LEAF / LEAFLET MARGINS

<b>A. ENTIRE</b>	= 63
1) SERRATE OR ENTIRE	= 21
2) CRENATE OR ENTIRE	= 2
<b>= 86 (38%)</b>	
<b>B. SERRATE</b>	= 65
1) DOUBLE SERRATE	= 13
2) SERRATE OR ENTIRE	= 21
3) SERRATE OR CRENATE	= 12
4) CRENATE OR ENTIRE	= 2
5) SERRATE OR DENTATE	= 2
6) SERRATE OR DOUBLE	
SERRATE	= 1
7) SERRATE & LOBED	= 13
8) DOUBLE SERRATE & LOBED	= 2
9) SERRATE OR DOUBLE	
SERRATE & LOBED	= 5
<b>= 136 (60%)</b>	
<b>C. LOBED</b>	= 26
1) SERRATE & LOBED	= 13
2) DOUBLE SERRATE & LOBED	= 2
3) SERRATE OR DOUBLE	
SERRATE & LOBED	= 5
<b>= 46 (20%)</b>	

Figure 46: Native tree leaf / leaflet margin types.

Values = number of species and percent of all 225 native tree species surveyed.

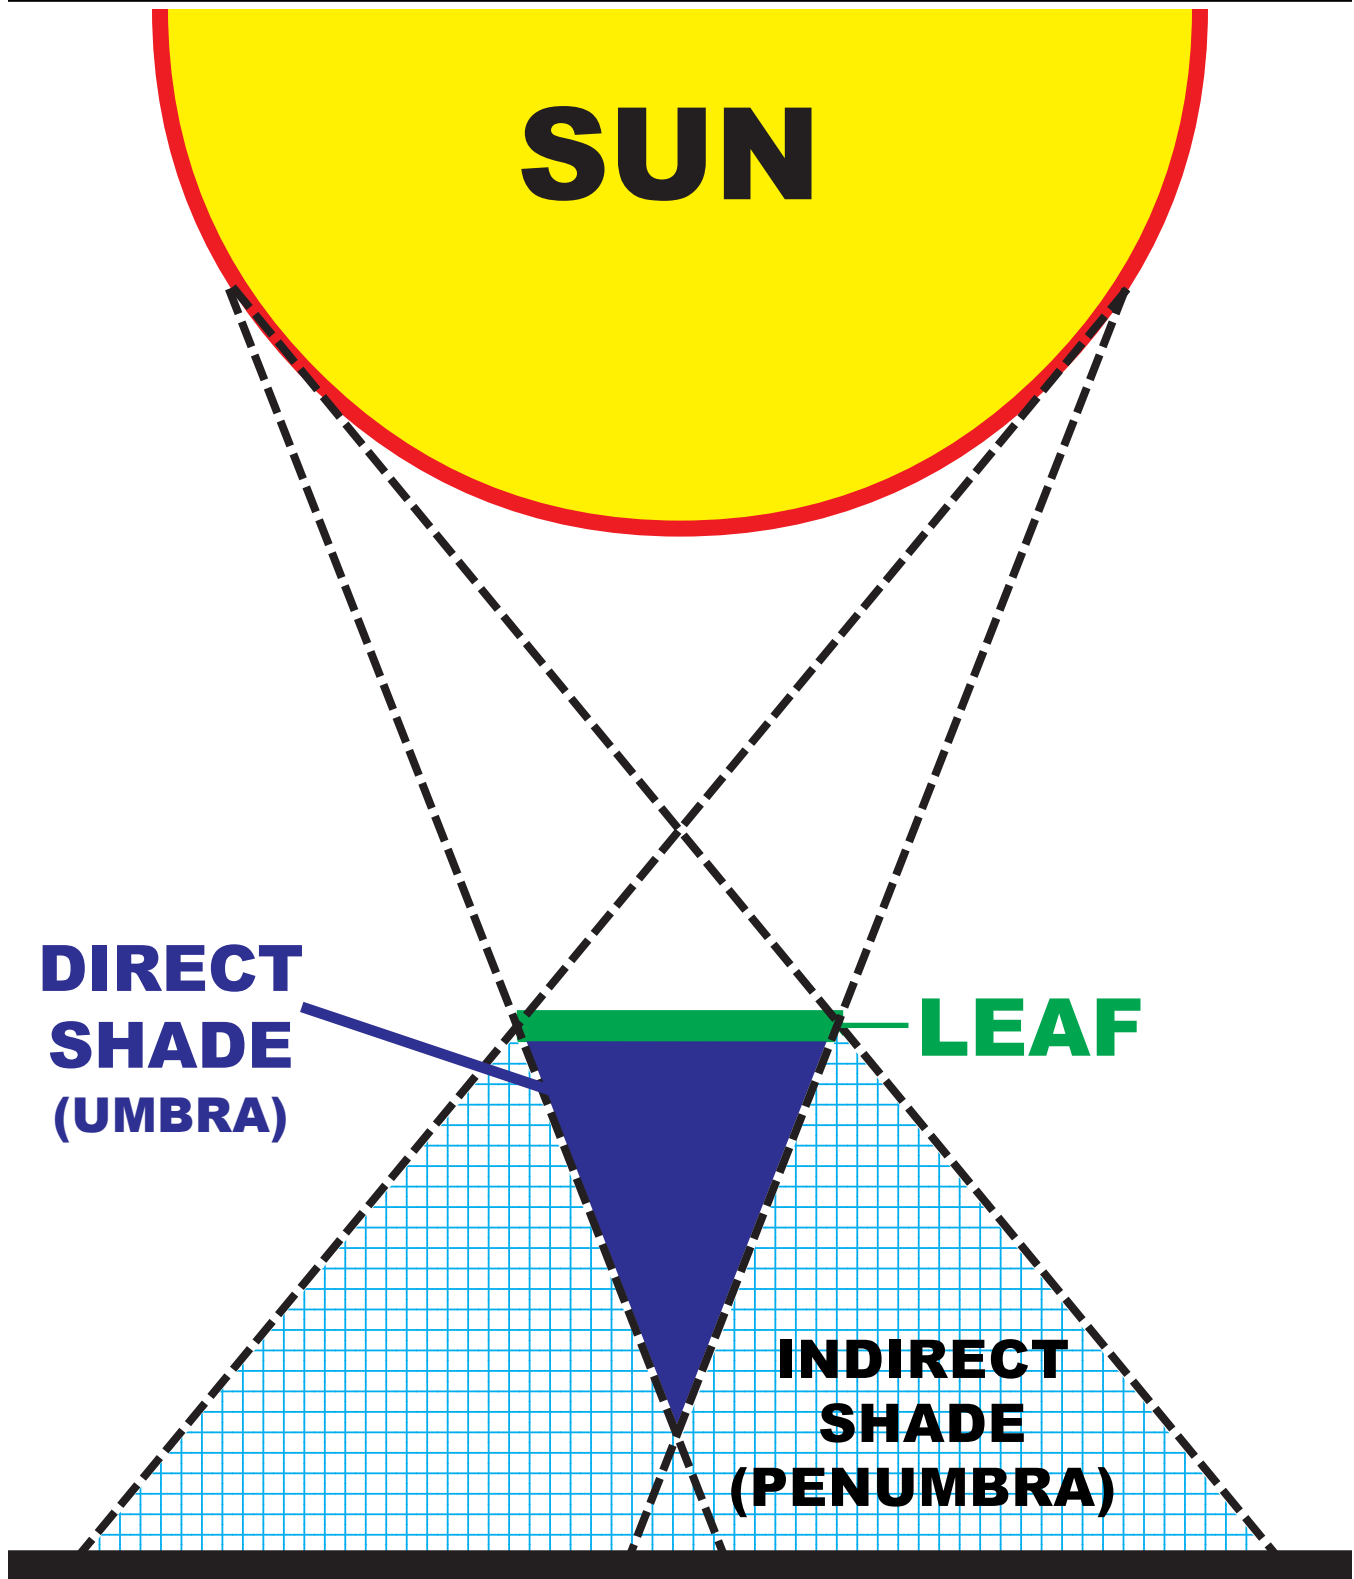

Figure 47: Direct (dense) shade volume (cone) behind a tree leaf with a given effective shade diameter.
